# R Code: F tests for ANOVA, More Nested Models

(Sleuth3 Sections 5.3 and 5.4)

### Spock Trials Example

#### Question: are the means for judges A through F equal?

 $H_0: \mu_1 = \mu_2 = \mu_3 = \mu_4 = \mu_5 = \mu_6$ 

 $H_A$ : At least one mean for a judge other than Spock is not equal to the others.

Note: if the null hypothesis is correct, there are effectively two groups:

- 1. All judges other than Spock's (they all have the same mean!)
- 2. Spock's judge

#### Tasks we need to do:

- 1. Fit the full model
- 2. Create a new variable in the data set representing the groups in the reduced model
- 3. Fit the reduced model
- 4. Call anova to compare the reduced model to the full model

#### Step 1: Fit the full model

```
fit_full <- lm(Percent ~ Judge, data = juries)</pre>
summary(fit_full)
##
## Call:
## lm(formula = Percent ~ Judge, data = juries)
## Residuals:
##
      Min

```

#### Step 2: Create a new variable in the data set representing the groups in the reduced model

The mutate statement below creates a new variable in the juries data frame called judge\_reduced. For each observation in the data set, judge\_reduced is "Other" if the Judge was in "A", "B", "C", "D", "E", or "F". Otherwise, judge\_reduced is "Spock's".

```
juries <- juries %>%
  mutate(
    judge_reduced = ifelse(Judge %in% c("A", "B", "C", "D", "E", "F"), "Other", "Spock's")
)
head(juries, 15) # just to check and make sure our new variable was created correctly
```

```
## # A tibble: 15 x 3
##
      Percent Judge
                       judge_reduced
##
        <dbl> <chr>
                       <chr>

                                             -5.67 1.03e-06 ***
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 7.056 on 44 degrees of freedom
## Multiple R-squared: 0.4222, Adjusted R-squared: 0.409
## F-statistic: 32.15 on 1 and 44 DF, p-value: 1.03e-06
```

Step 4: Call anova to compare the reduced model to the full model

#### anova(fit\_reduced, fit\_full)

```
## Analysis of Variance Table
##
## Model 1: Percent ~ judge_reduced
## Model 2: Percent ~ Judge
## Res.Df RSS Df Sum of Sq F Pr(>F)
## 1 44 2190.9
## 2 39 1864.5 5 326.46 1.3658 0.2582
```

Because interpretation is important: what is the conclusion? Does this prove that the other judges had the same mean percent of women in their jury pools?

## **More F Test Examples (part 1)**

In all cases the full model has a separate mean for all 7 judges:  $\mu_1$  for judge A,  $\mu_2$  for judge B,  $\mu_3$  for judge F, and  $\mu_7$  for Spock's judge.

We estimate this model with: fit\_full <- lm(Percent ~ Judge, data = juries)

The sample size is n = 46, so the degrees of freedom for the full model is: 46 - 7 = 39
